

Global temperatures
are warming fast.

Warming is causing
more hurricanes and
typhoons to become
more devastating.

What are hurricanes and typhoons?

Hurricane are categorized by wind speed

The faster the winds, the more
destruction they cause.

You might remember some storm names!

Temperatures are going up fast!

Big storms are correlated with rising temperatures

What can we do?

To have less frequent big storms, we must slow, stop and reverse the upward trend of temperature rise.

1. Switch to renewable energy to reduce carbon dioxide emissions
2. Improve energy efficiency everywhere
3. Reduce deforestation, promote reforestation
4. Shift to sustainable agriculture and diets
5. Electrify transportation
6. Support climate policies and innovations

Slide Notes

- Slide 2: Tell the story of what it was like to be alive and in NYC before and after Hurricane Sandy, the tunnels, the banks, the scuba divers, etc.
- Slide 3: **A hurricane (or typhoon, depending on where it occurs) is a huge storm system with strong winds and heavy rain. It forms over warm ocean water, typically when warm, moist air rises and cooler air rushes in to replace it. This creates a spinning system of clouds and wind. The jet stream and other air currents can steer these storms.** Both are tropical cyclones—just with different names depending on the part of the world they form in.
- Slide 4: Explaining tracking, becoming named storms, and introduce storm formation relative to warm waters.
- Slide 5: Ask if anybody has ever heard stories of hurricanes, and what their names were. Talk about your coworkers in Florida
- Slide 6: Explain the baseline 1951 to 1980 where was pretty flat. And explain what a baseline is and why we need one. And explain how this is a relative change chart. **“Our planet has been getting steadily warmer since we started tracking temperatures. Think of it like a fever - Earth's temperature has climbed from about 0.4°F above normal to almost 2°F above normal. That might not sound like much but imagine if your normal body temperature of 98.6°F suddenly became 100.6°F - you'd definitely feel sick! This warming has sped up dramatically since 2000.”**
- Slide 7: Show how all the dots of cat 4 and cat 5 hurricanes, and how they are going up since 1980. Show the numbers right y axis. **“We are seeing more super-strong hurricanes (Categories 4 and 5). While the number of these powerful storms goes up and down naturally from year to year, we've had some record-breaking hurricane seasons since 2000. The years 2005 and 2017 were particularly active, with more major hurricanes than we typically see. These stronger storms are showing up more often as ocean temperatures rise, though other factors affect hurricane formation too.”**
- Slide 8: Open up discussion, talk about why.
